Dijkstra algorithm & Huffmann coding

Unit 4

Purpose of Huffman Coding

- Proposed by Dr. David A. Huffman in 1952
  - *“A Method for the Construction of Minimum Redundancy Codes”*
- Applicable to many forms of data transmission
  - Our example: text files

The Basic Algorithm

- Not all characters occur with the same frequency!
- Yet all characters are allocated the same amount of space
  - 1 char = 1 byte, be it e or X

The Basic Algorithm

- Code word lengths are no longer fixed like ASCII.
- Code word lengths vary and will be shorter for the more frequently used characters.

The (Real) Basic Algorithm

1. Scan text to be compressed and tally occurrence of all characters.
2. Sort or prioritize characters based on number of occurrences in text.
3. Build Huffman code tree based on prioritized list.
4. Perform a traversal of tree to determine all code words.
5. Scan text again and create new file using the Huffman codes.

Building a Tree Scan the original text

- Consider the following short text:

  Eerie eyes seen near lake.

- Count up the occurrences of all characters in the text

Building a Tree Scan the original text

Eerie eyes seen near lake.

- What characters are present?

E e r i space
y s n a r l k .

Building a Tree Scan the original text

Eerie eyes seen near lake.

- What is the frequency of each character in the text?

Char	Freq.
E	1
e	8
r	2
i	1
space	4

Char	Freq.
y	1
s	2
n	2
a	2
l	1

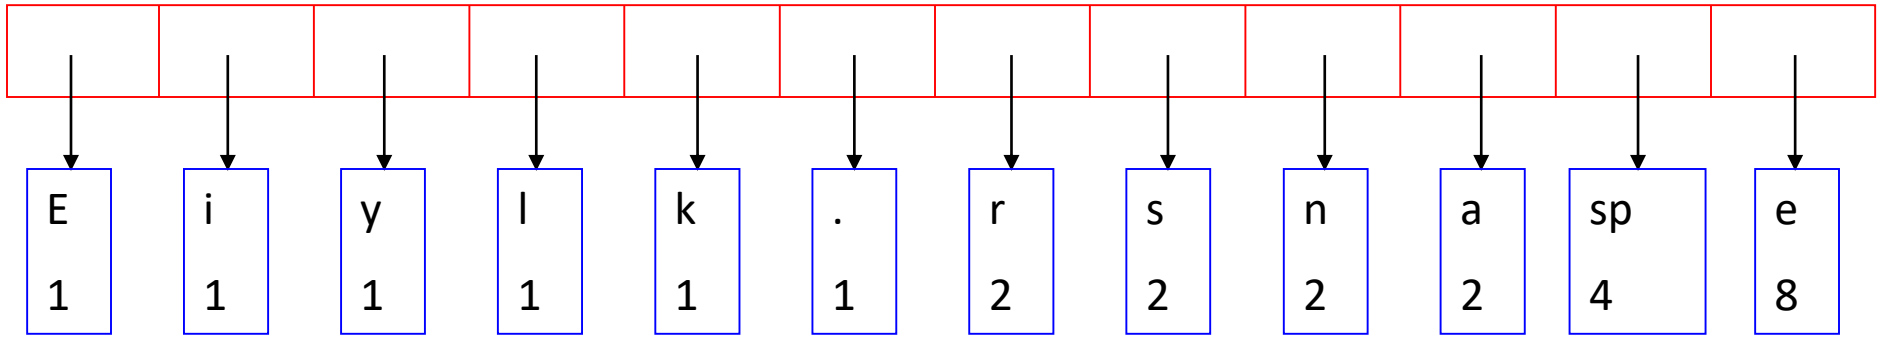
Char	Freq.
k	1
.	1

Building a Tree Prioritize characters

- Create binary tree nodes with character and frequency of each character
- Place nodes in a priority queue
  - The lower the occurrence, the higher the priority in the queue

Building a Tree

- The queue after inserting all nodes

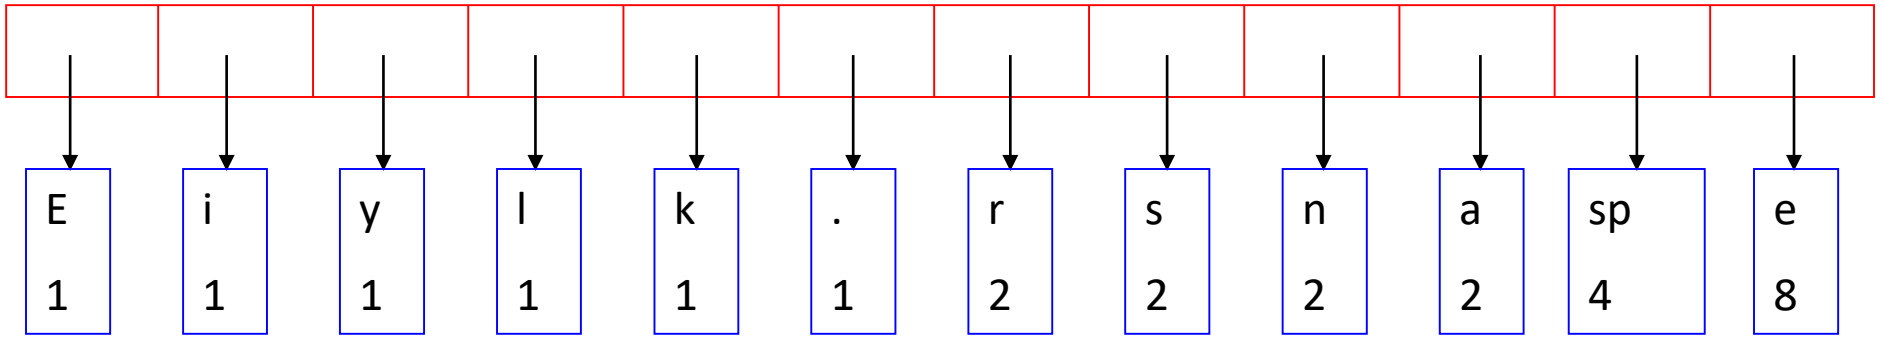


- Null Pointers are not shown

Building a Tree

- While priority queue contains two or more nodes
  - Create new node
  - Dequeue node and make it left subtree
  - Dequeue next node and make it right subtree
  - Frequency of new node equals sum of frequency of left and right children
  - Enqueue new node back into queue

Building a Tree



Building a Tree

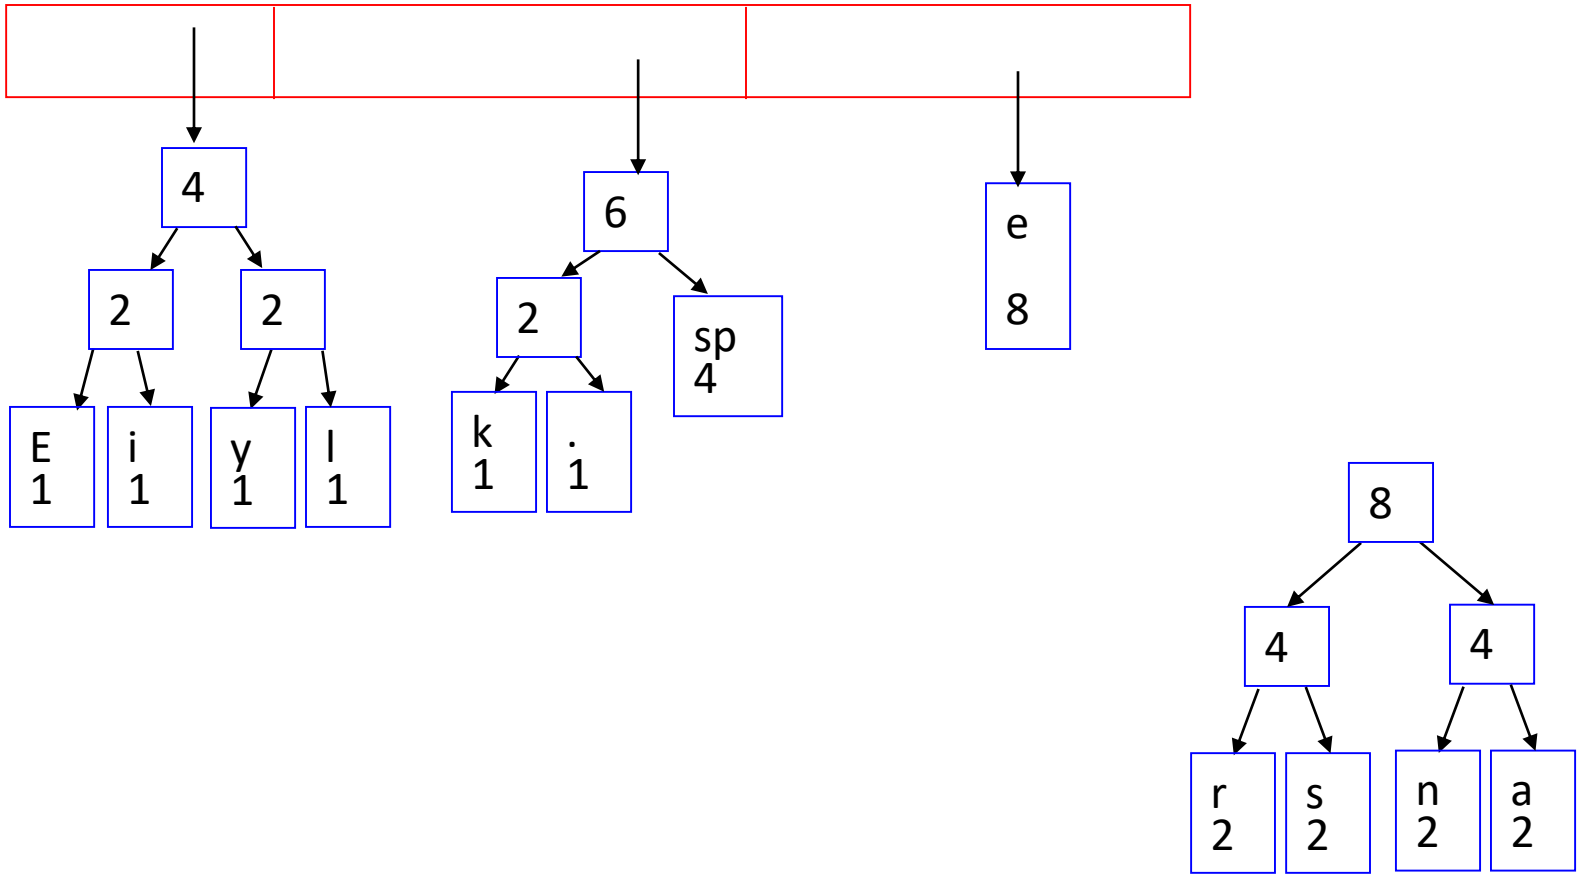
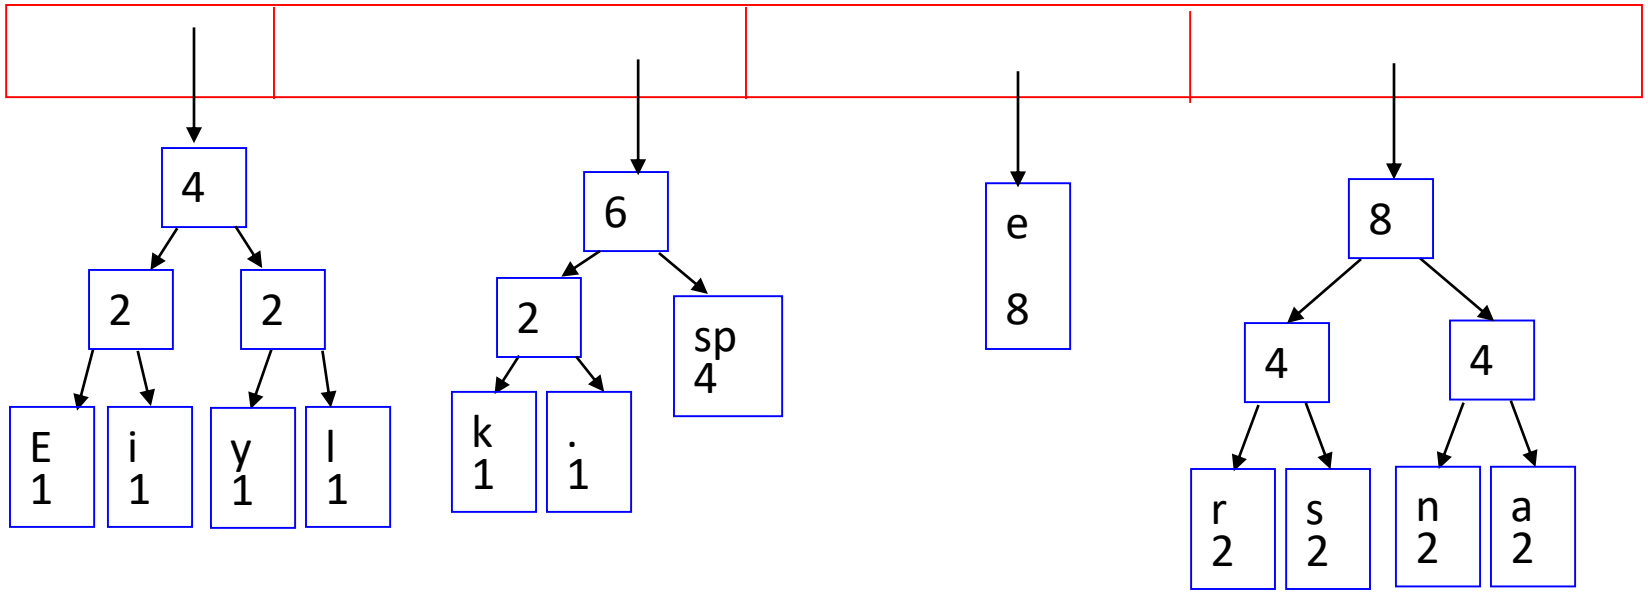
What is happening to the characters with a low number of occurrences?

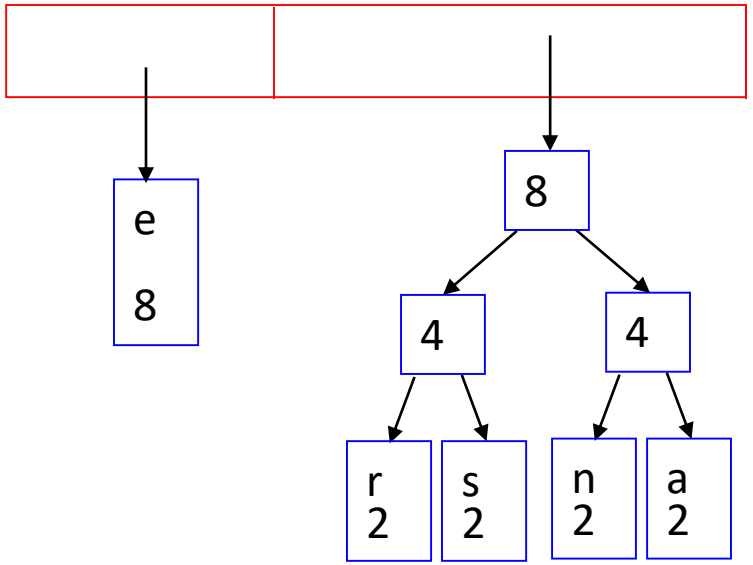
Building a Tree

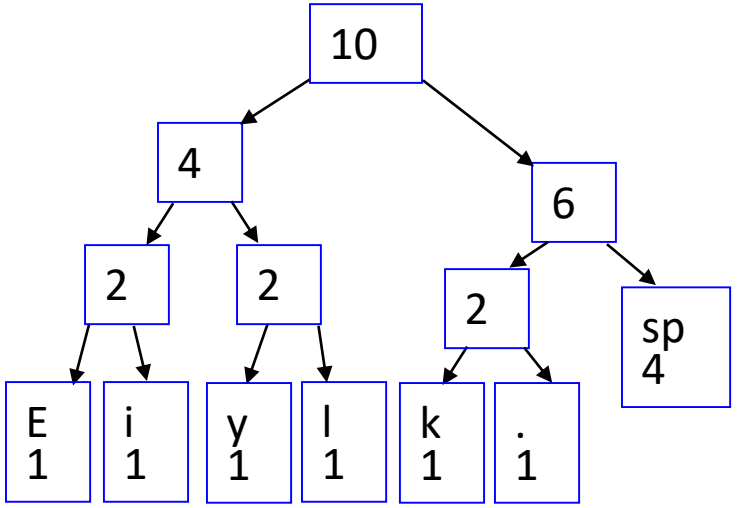


Building a Tree

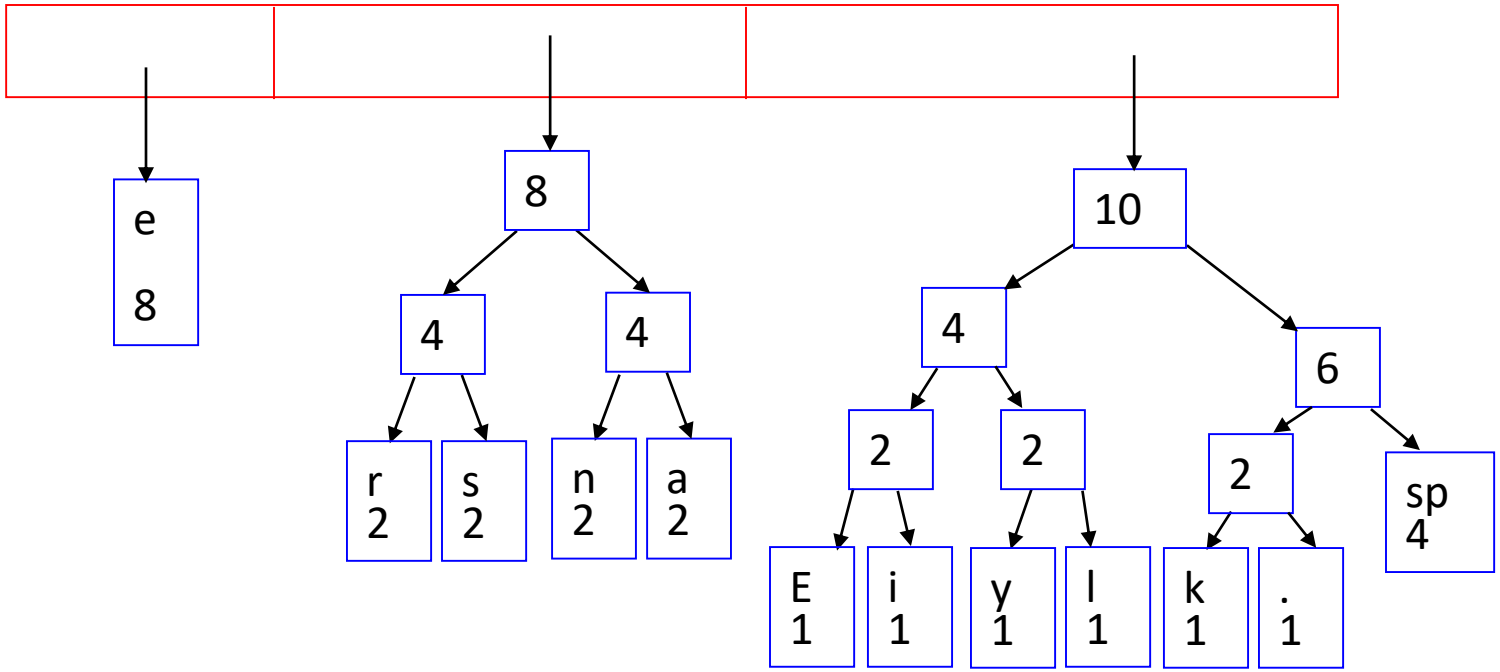


Building a Tree

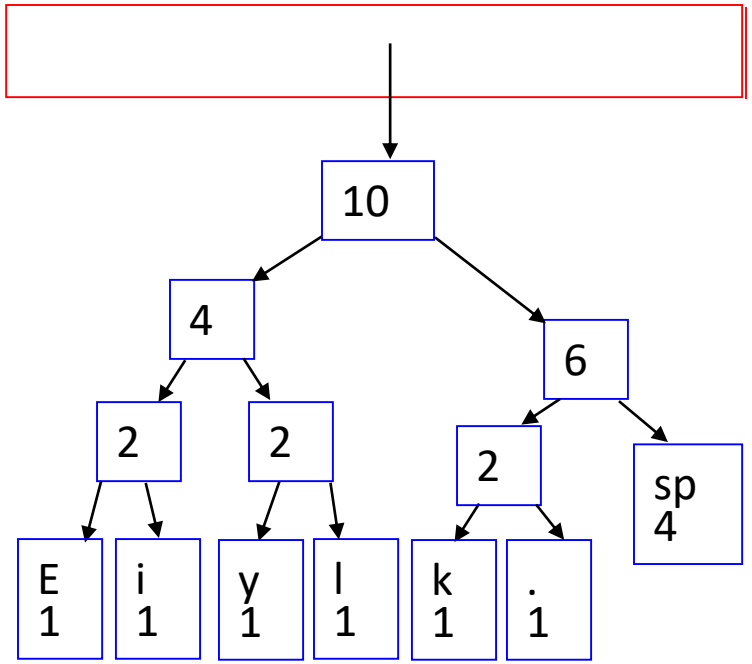


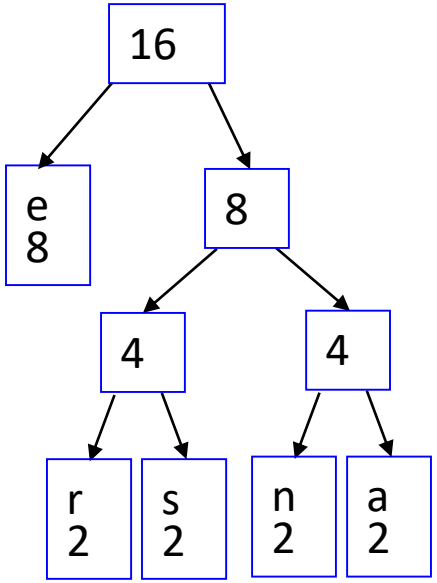


Building a Tree

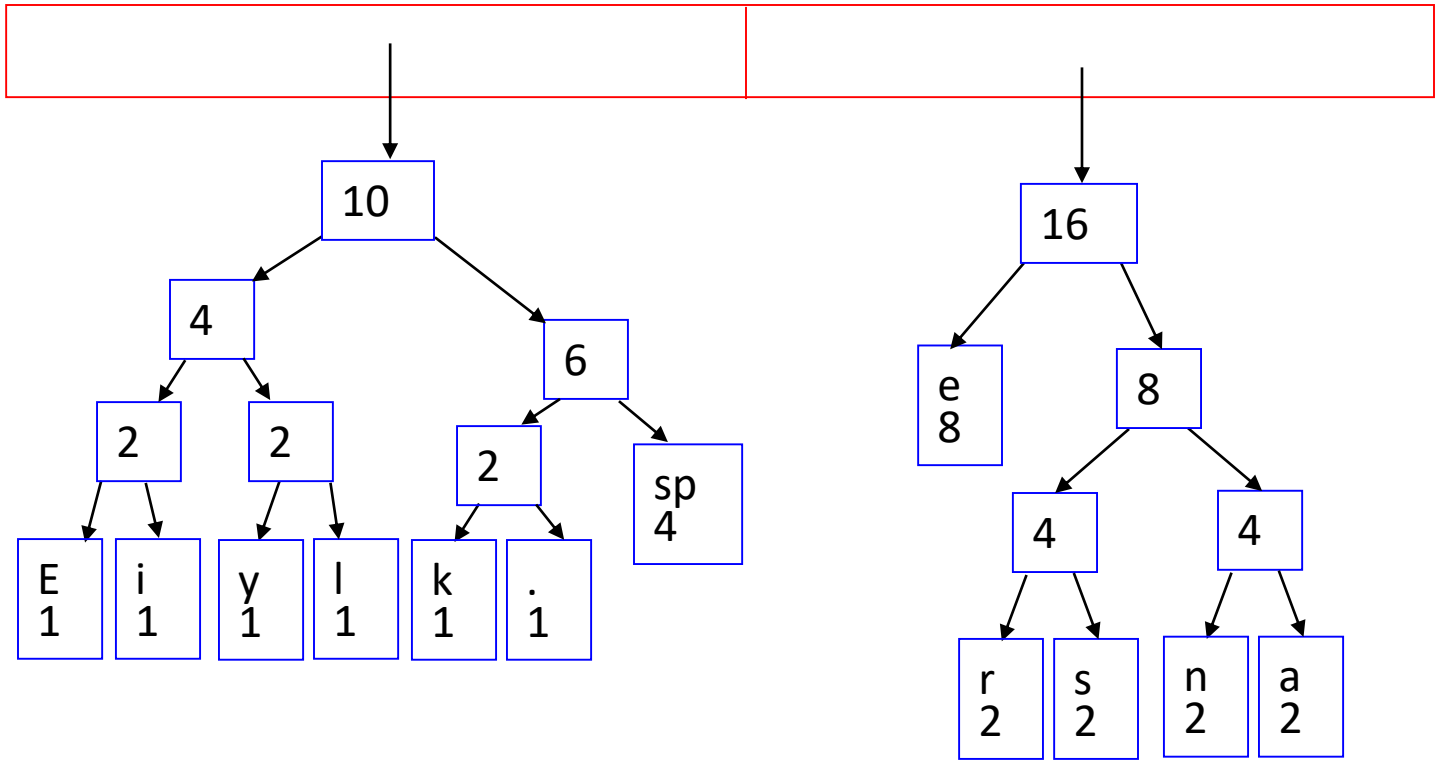


Building a Tree

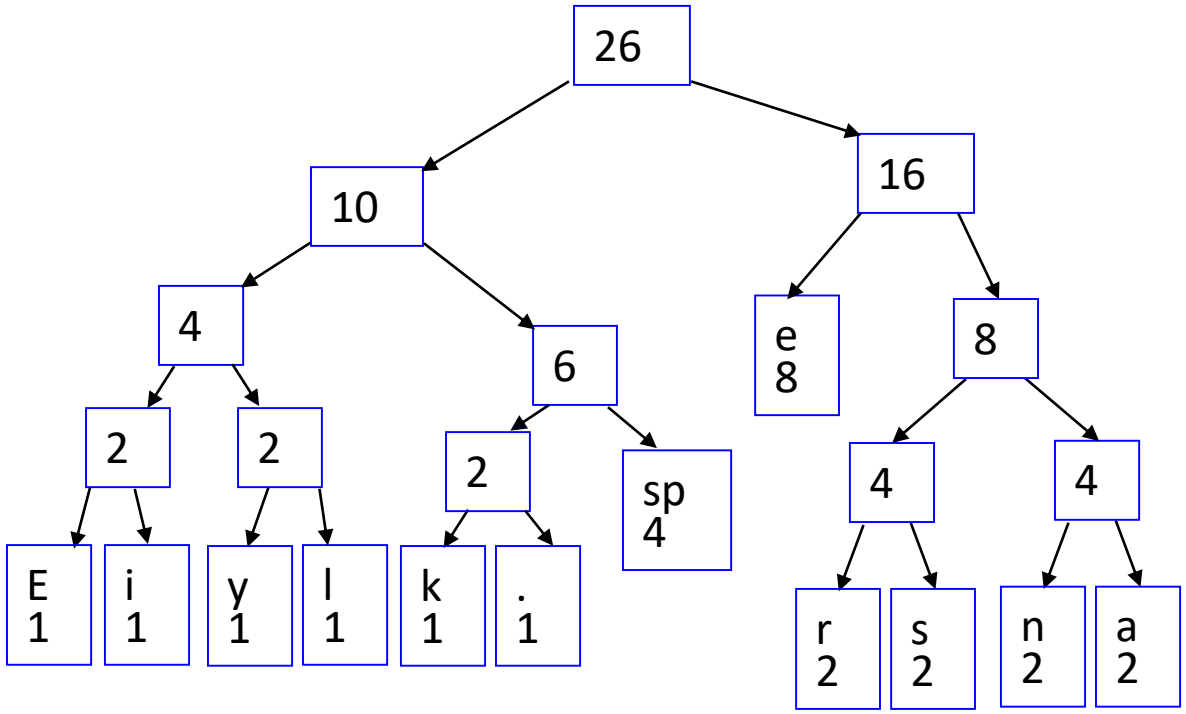




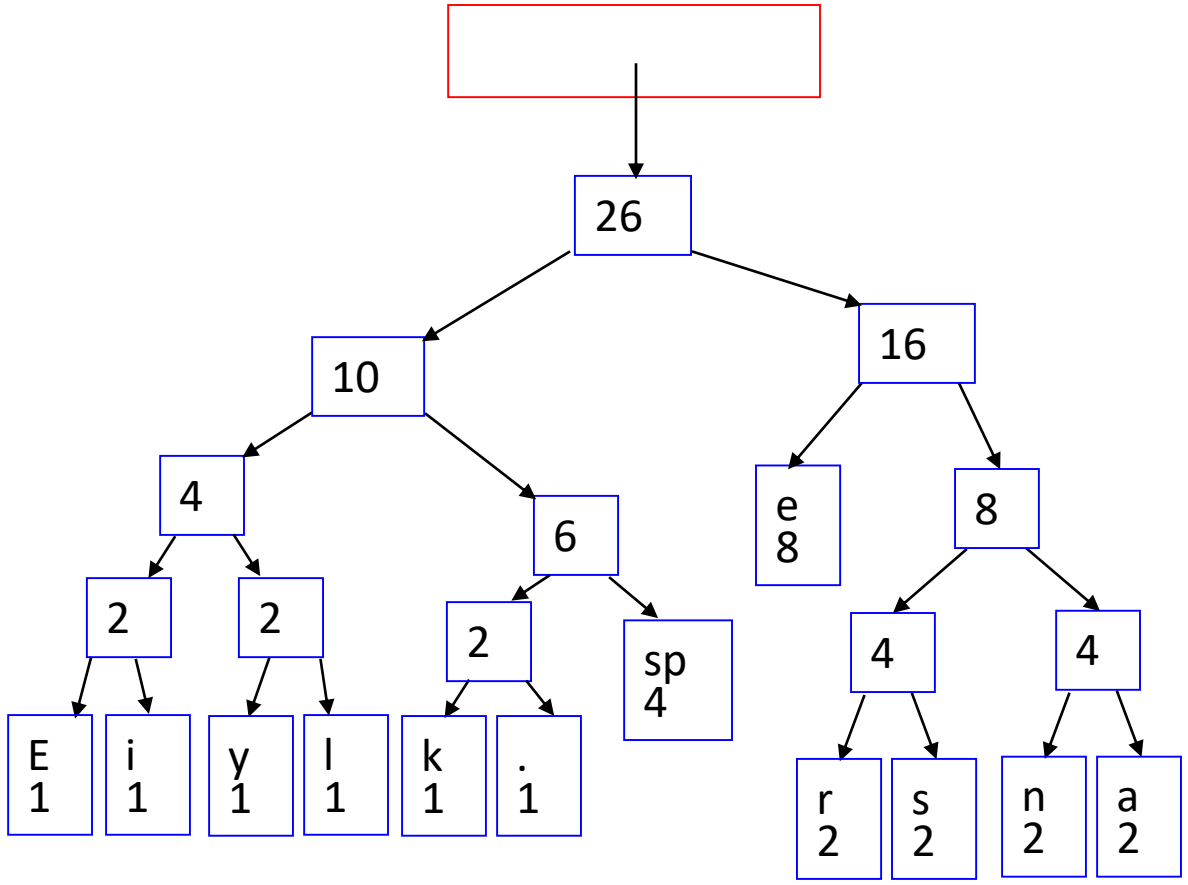
Building a Tree



Building a Tree



Building a Tree



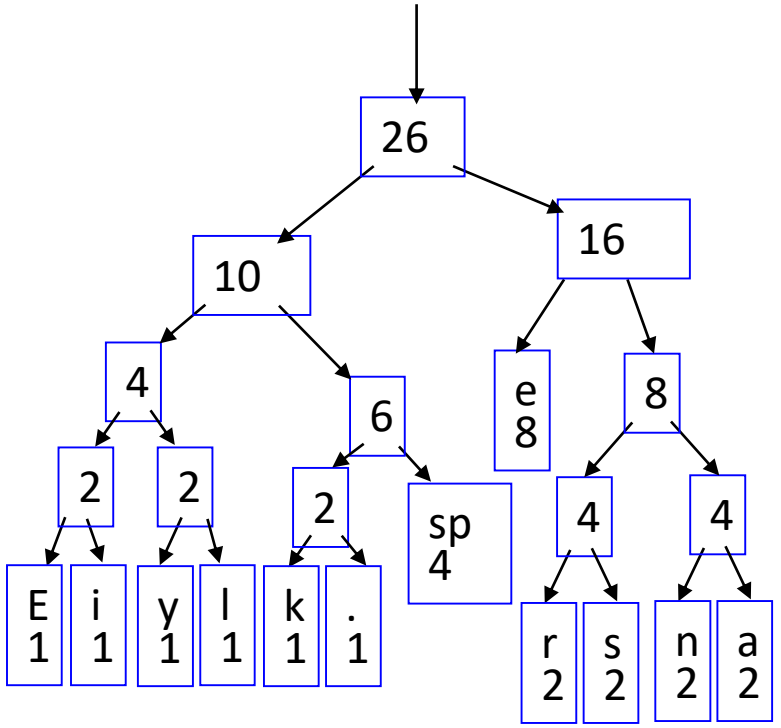
After enqueueing this node there is only one node left in priority queue.

Building a Tree

Dequeue the single node left in the queue.

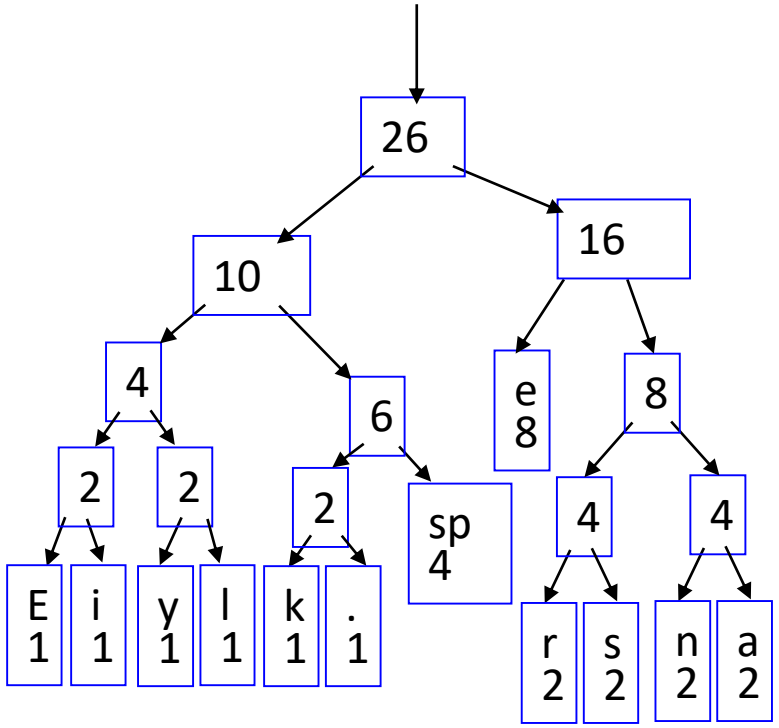
This tree contains the new code words for each character.

Frequency of root node should equal number of characters in text.



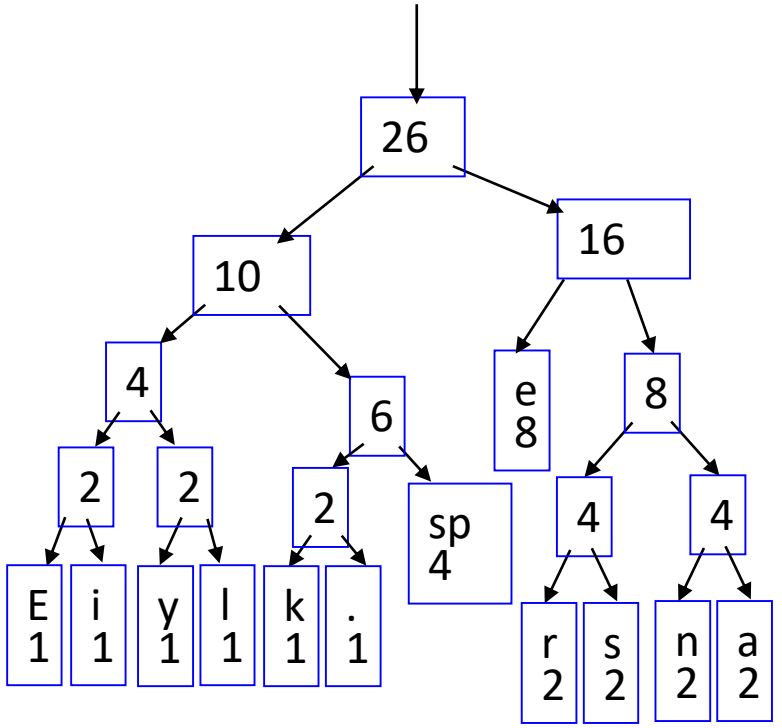
Encoding the File Traverse Tree for Codes

- Perform a traversal of the tree to obtain new code words
- Going left is a 0 going right is a 1
- code word is only completed when a leaf node is reached



Encoding the File Traverse Tree for Codes

Char	Code
E	0000
i	0001
y	0010
l	0011
k	0100
.	0101
space 011	
e	10
r	1100
s	1101
n	1110
a	1111



Encoding the File

- Rescan text and encode file using new code words

Eerie eyes seen near lake.

```
000010110000011001110001010110110100
111110101111110001100111111010010010
1
```

- Why is there no need for a separator character?

.

Char	Code
E	0000
i	0001
y	0010
l	0011
k	0100
.	0101
space	011
e	10
r	1100
s	1101
n	1110
a	1111

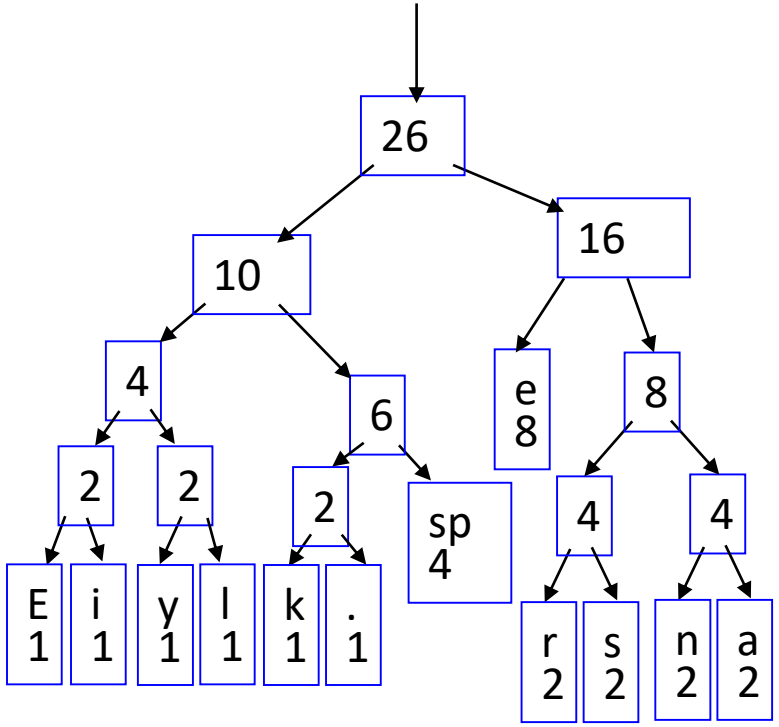
Encoding the File

- Have we made things any better?
- 73 bits to encode the text
- ASCII would take 8 * 26 = 208 bits

```
0000101100000110011100010101101101001111110101111110001100111111010010010 1
```

Decoding the File

- Once receiver has tree it scans incoming bit stream
- 0 ⇒ go left
- 1 ⇒ go right



Summary

- Huffman coding is a technique used to compress files for transmission
- Uses statistical coding
  - more frequently used symbols have shorter code words
- Works well for text and fax transmissions
- An application that uses several data structures

Thank You !!!
